Slav, *n* One belonging to any of the Slavonic groups of Aryans These are all domiciled in Europe, except the Russians of Siberia and a large number of emigrants settled in America Geographically they form three main groups (1) **Eastern Slavs**, or Russians, (2) **Northwestern Slavs**, including the Poles, Lusatians, Wends, Czechs, Moravians, Slovaks, and Polabians, and, (3) **Southern or Jugoslavs**, including the Serbo-Croatians, Bulgarians, and Slovenes They are the most numerous race in Europe, amounting to about 140,000,000 souls Physically, the type is not sufficiently clear to throw much light upon the history of the race, most modern Slavs being brachycephalic, of medium height, and of dark complexion, whereas the evidence at hand seems to indicate that the race was formerly dolichocephalic and differed but little from other Germanic tribes Their original habitat seems to have been the basins of the Vistula and other rivers to the northeast of the Karpathians. See SLAVONIC, and plate of RACES OF MANKIND, at MAN

> There is no evidence that the *Slavs* made any considerable migration from their first home until the 1st century A D The sudden appearance in the 6th-century writers of definite names for the *Slavs* and their divisions means that by then the race had made itself familiar to the Græco-Roman world and had some time before come into contact with civilisation

snake', *n* **1.** An ophidian reptile, a serpent

Snakes differ from lizards chiefly in having a greatly elongated body in the absence (with rare exceptions) of limbs or limb-girdles and in having a specialized swallowing-apparatus The skull is loosely composed the bones, especially of the lower jaw, being suspended and connected by elastic ligaments, admitting of the deglutition of relatively large objects The teeth are numerous small, conical, recurved and not used for chewing the animal seizing its prey and swallowing it by gradually advancing its hold This process is aided by a copious flow of saliva The bite of most snakes is quite harmless to large animals but in some as the vipers coral-snakes and sea-snakes there have been developed much enlarged fangs hollow or grooved, with which a stabbing bite may be inflicted These fangs are connected with venom-glands from which a deadly poison flows into the punctures they make The skin of serpents is covered with more or less deeply embedded scales, but is devoid of osteoderms This skin is sloughed off at intervals (annually in adult individuals) permitting growth The nervous system of ophidians is highly organized their senses are keen, and they display considerable intelligence and tamability The eyes are large and clear the ears altho without external openings, possess good hearing, and the nose is highly sensitive, most snakes depending mainly upon scent in seeking and following their prey, which is seized by a swift dart of the head and neck, the after part of the body clinging firmly to some support The forked tongue is an exceedingly delicate instrument of touch The distal points of the ribs on each side are connected in pairs with the ends of the gastrosteges and locomotion is effected by a muscular hitching forward of these rib-points and ventral scales combined with pressure on the ground or other support A few, as the vipers, are too heavy for climbing or for great speed but most snakes move swiftly, are extremely agile as climbers, and good swimmers All are carnivorous, and feed upon living prey almost exclusively, yet are able to endure long fasts Snakes are most numerous and of greatest size in the tropics, diminishing in numbers and variety northward until they disappear at about the summer isotherm of 30° In cold countries they hibernate in underground holes often in entwined bunches The majority of the class reproduce their kind by eggs which are few in number, large and covered with a leathery shell, and which they bury in dung-hills rotting logs or warm earth, to be hatched by natural heat, but most of the poisonous and some colubrine snakes bring forth their young alive

sol'id, *n* 1. A mass of matter of which the shape can not be changed permanently and greatly without fracture See STATES OF MATTER, under MATTER

It is impossible to draw a hard and fast line between solids and liquids In physics the two are distinguished by the yielding of a liquid to any force, no matter how small, if it is only given time enough, but the same body may act as solid and as liquid to different forces Thus, shoemakers wax, which in common language would be called a solid, is classed by physicists as a very viscous liquid as it will flow appreciably by its own weight in the course of several months, but it may be fractured like a solid by a sudden blow Again, metals may be made to flow under very great pressure like liquids The shape of a solid can be altered only temporarily by force unless that alteration exceeds its limit of elasticity, when it becomes permanent On the molecular theory these peculiarities are explained by supposing the molecules of solids to be describing closed curves in systems or groups, which tend to preserve their identity till a very great force causes a rearrangement of the molecules in new groups

The sonnet came into English verse from Italy, in the sixteenth century There are two principal forms (1) The so-called **Italian sonnet** consists of 14 iambic pentameter lines, arranged thus an octave, riming *a b b a, a b b a,* and a sestet, riming *c d e, c d e,* or *c d e, d c d,* or *c d e, d c e,* or *c d e, e d c* A rime in the last couplet is permissible, but disapproved by most critics The octave is supposed to introduce the main idea or sentiment, which the sestet develops, or illustrates by comparison or contrast (2) The **Elizabethan or Shakespearian s** consists of 14 iambic pentameter lines, arranged in quatrains of interwoven rime and closing with a rimed couplet

In the sense of def 1, a vibration that does not affect the ear, either because of its qualities or because no ear is within its range, causes no sound In that of def 2, all such are sounds, and are hence classified as **audible** and **inaudible** All harsh, sudden sounds are called **noises**, and are due to irregular or discontinuous vibration Sounds due to regular vibration, called **musical sounds**, possess three qualities (1) **intensity** due to the extent of the vibration, (2) **pitch**, due to its rapidity, and (3) **timbre**, or **color**, due to its form The vibrations audible to the human ear range from 24 to about 40,000 a second Sound travels at the rate of 1,090 feet a second in air, and at widely varying rates in different media In $4\,T/12$ etc show the relative positions of hydrogen the rate is the same particles in motion at different 4 190 feet in water, periods of time T being the periodic time 4 730 feet, in copper, The alternating impressions and rarefactions of the particles move from left to right. 12,200 feet, in iron 15,700 feet A rise in temperature produces an increase of velocity, the increase being about two feet per second for every degree Fahrenheit in the case of air Sound-waves may be reflected, refracted, and diffracted like light-waves They may also interfere See BEAT 7, and compare TONE

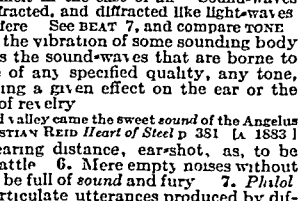

Diagram Showing Motion of Sound-waves

The points of the line to the right of A represent equidistant particles at rest, while those to the right of $0\ T/12$, $2\ T/12$, $4\ T/12$ etc show the relative positions of the particles move from left to right.

Syn., noise, note, tone *Sound* is the most comprehensive word, applying to anything that is audible *Tone* is *sound* considered as having some musical quality or as expressive of some feeling *noise* is *sound* considered without reference to musical quality or as distinctly unmusical or discordant Thus, in the most general sense *noise* and *sound* scarcely differ, and we say almost indifferently "I heard a *sound*" or "I heard a *noise*" We speak of a fine, musical, or pleasing *sound*, but never thus of a *noise* In music, *tone* may denote either a musical *sound* or the interval between two such *sounds*, but in the most careful usage the latter is now distinguished as the "interval," leaving *tone* to stand only for the *sound* *Note* in music strictly denotes the character representing a *sound*, but in loose popular usage it denotes the *sound* also, and becomes practically equivalent to *tone* Aside from its musical use, *tone* is chiefly applied to that quality of the human voice by which feeling is expressed as, he spoke in a cheery *tone*, the word is similarly applied to the voices of birds and other animals and sometimes to inanimate objects As used of a musical instrument, *tone* denotes the general quality of its sounds, collectively considered See NOISE

2. The abstract possibility of extension, that which is characterized by dimension, continuous and boundless extension This conception of *space* has two principal and connected but largely different forms according as it is framed to meet the practical demands of mathematics in the geometrical branches or is made the subject of critical examination from the standpoint of its psychological origin, with a view to determine its metaphysical significance (1) *Math* Continuous and boundless extension regarded as a sort of *vacuous entity* in which extended things may exist and move about In the operations of Euclidean geometry all the conditions of the pure and applied science are satisfied with the assumption that space is actually such a three-dimensional vacuous entity, **three-dimension space**, as the experience of our senses with the extensions and extension-relations of sensible objects assumes it to be That is, space itself exists in three dimensions, but it must be conceived of as boundless, continuous throughout, and, in itself considered devoid of all actually extended real objects or things The non-Euclidean, or new geometry, finding that the mathematical operations of a geometrical character can be equally well satisfied by making assumptions contradictory of many of the postulates and axioms of Euclid has developed a theory of a possible **four-dimensioned**, or even *n*-**dimensioned s.** But such space, if it exists at all, whether as itself a vacuous entity or as a condition of extended bodies can not be conceived of by us or made to harmonize with our experience as dependent upon the perception of things existent and moving in three-dimensioned space. (2) *Philos* While the mathematical doctrine of space is naïvely metaphysical, philosophy has from very ancient times raised and discussed the problem of the reality of space apart from space-filling objects Up to the critical metaphysics of Kant the skeptical and the dogmatically realistic answers to this problem divided the field between them the former maintaining the illusory and purely subjective nature of the conception of space and the latter accepting in the main the assumptions of common sense so called and of the Euclidean geometry Descartes regarded space as the essence of bodily substance Spinoza considered it as one aspect or attribute of universal substance Leibnitz described it as an actual relation or principle of the ordering of coexistent phenomena With the keen psychological analysis of Berkeley the modern study of the origin of the conception of space began to be pursued with more thoroughness and by diligence in the use of experimental and theoretical methods in the hands of many competent psychologists there has come to be a fair amount of agreement as to how, by a process of abstraction based upon experience with the visual tactical kinesthetic, and stereognostic senses this conception is, as a matter of fact obtained As to the definitely metaphysical problem with its inquiry into what in reality corresponds to our mental image or thought of space three principal answers with various shades of meaning between are current in modern philosophy (1) The *realistic* which holds that space is itself some sort of a three-dimensioned boundless continuous but vacuous entity In which extended real beings exist and move (2) the *idealistic* which regards space as the a priori or ideal form given by the mind to all sensuous objects in correspondence with the form in which the Absolute Idea is realizing itself by a special kind of activity (3) the *materialistic* and *agnostic*, which regards space as the impression made upon our minds by things but concludes that the problem of the correlated reality like all ontological problems transcends the limits of knowledge or tenable speculation that is, space as a reality is inexplicable or irrational

spe'cies, 1 *spī'shīz or -shı-īz,* 2 *spē'shēş or -shı-ēş* (XIII), *n sing & pl* **1.** *Biol* (1) A classificatory group of animals or plants subordinate to a genus, and having members that differ among themselves only in minor details of proportion and color, and are capable of fertile interbreeding indefinitely

In the kingdoms of organic nature species is founded on identity of form and structure, both external and internal, and specifically characterized by the power of the individuals to produce beings like themselves who are also in turn productive, while in the mineral kingdom mineralogical and chemical species are determined by identity of composition, and in crystallization and physical characters Species usually show a considerable range of variation and often have some form of polymorphism The word *species* was first introduced into biology by the English botanist John Ray, and popularized by the Swedish naturalist Linnæus The earlier writers considered species to be fixed and immutable creations, intermediate types being regarded as hybrids or abnormalities, but the French naturalist J B P A de Lamarck contended for the transmutation of species by natural processes, and when Charles Darwin's *Origin of Species* appeared in 1859 it profoundly influenced the views of biologists, Darwin contending that new species originated from preexisting species by gradual modifications due to accidental variations which prove advantageous in the struggle for existence and therefore survive and are perpetuated in the individual who is thus chosen by a natural selection J G Romanes (1848–1894) showed the importance of segregation either reproductive or by some physical barrier in the origin of species Hugo de Vries (1848–) has shown the existence within the limits of the older taxonomic species of a host of elementary species which, if self-pollinated, reproduce true to type O F Cook (1867–) has shown that evolution may proceed without the origination of new species (that speciation and evolution are not synonymous), and that normal species consist of a considerable number of slightly or even considerably different strains These heteristic forms persist in spite of free interbreeding, which converts the whole species into a network of descent

The conception of species is the most vital one in biology and has been the subject of animated controversy, some physiologists denying the objective existence of species, while almost all taxonomists and most field naturalists and evolutionists consider the species as being a real biologic unit, having definite and provable objective existence Compare EVOLUTION, HEREDITY, MUTATION, NATURAL SELECTION

In modern practice systematists no longer regard *species* as more than as an artificial rank in classification to be applied chiefly for reasons of convenience so that the word is reverting to its older logical significance
Encyc Brit 11th ed vol XXV p 616

(2) In evolutionary biology, a coherent group of interbreeding organisms Species are segregated in some way from other groups, and usually exhibit considerable heteristic diversity and often have also some form of polymorphism **2** *Logic* (1) A group of individuals or objects agreeing in some common attribute or attributes and designated by a common name a conception subordinate to a higher conception called a *genus* (compare GENUS), *e g, man* is a species of the genus *rational beings* (2) In definition, the common attribute or attributes of a species, differentia The statement of the genus and species of a term constitutes its *logical definition* or *essence* Compare DIFFERENTIA; DIFFERENCE **3** Hence, in common language, a kind, sort, variety, form, as, the lion is a *species* of quadruped, honesty is a *species* of virtue **4.** A mental image, or phantasm, considered as having the likeness of some object in nature, an idea, implying a similitude of some reality In medieval philosophy, especially following the lead of Thomas Aquinas the species is first operative in knowledge by the senses (**species sensibilis**), and, as this, may be conceived of either as a physical motion (s **impressa**) or as the translation of this physical activity by the mind into a sensuous construction (s **expressa**). But real cognition is reached only when the process results in intellectual apprehension (s **intelligibilis**), and this, in turn, may be considered either as an aroused activity of the intellect (s **intelligibilis impressa**), or as a product of the intellect (s **intelligibilis expressa**) Thus all knowledge is held to involve both senses and intellect, and both as regarded from the points of view of their activity and their impressibility

Spectroscopes consist in general of three essential parts: (1) a collimating tube bearing at one end a slit of adjustable width through which the light is admitted, and at the other end lenses for making the rays parallel as they pass on to (2) that part of the instrument in which dispersion takes place, forming the spectrum, as a prism, a train of prisms, or a diffraction grating and (3) a small telescope through which the observer views the spectrum, and which can be moved to view different orders of spectra or different parts of the same spectrum In addition, there is usually a device for the measurement of the spectrum, as by throwing upon it the image of a minute scale Usually, owing to the deviation of the light by the prism, the collimating- and observing-tubes of a refracting spectroscope make a considerable angle with each other, but in a form (often portable) called the **direct-vision spectroscope** all these parts are contained in a single straight tube, the train of prisms being composed of different kinds of glass so arranged that deviation is corrected but not dispersion If a Rowland concave grating is used, no observing-telescope is necessary, the grating forming a real image, which may be received on a screen or a photographic plate, or viewed with a simple eyepiece The resulting spectrum may be so long that the eyepiece must be mounted on a carriage that travels along a miniature railway For the uses of the spectroscope, see SPECTRUM ANALYSIS [< SPECTRO- + -SCOPE]

While our estimates of the lateral movements of stars depend upon our very uncertain knowledge of their distance the *spectroscope* gives the motions of approach and recess irrespective of other motions excepting that of the earth

spec-tros'co-py, 1 spek-tros'ko-pi *or* spek'tro-skō'pi, 2 spĕc-trŏs'co-py *or* spĕc'tro-scō"py (XIII), *n* The branch of physical science that treats of the phenomena observed with the spectroscope, or those principles on which its action is based, also, the art of using the spectroscope

Spectrum analysis thus passed quickly out of the stage in which its main purpose was analysis' and became our most delicate and powerful method of investigating molecular properties the old name being no longer appropriate we now speak of the science of *spectroscopy* *Encyc Brit* 11thed vol xxv p 619

spec'trum, 1 spek'trum, 2 spĕc'trŭm, *n* [SPECTRA, *pl*] **1.** *Physics* An image, visible or invisible, formed by rays of light or other radiant energy, in which the parts are arranged according to their refrangibility or wave-length, so that all of the same wave-length fall together, while those of different wave-lengths are separated from each other, forming a regular progessive series

A substance existing in the form of an incandescent gas may be identified by the arrangement and position of the bright lines in its spectrum which are the same for every substance Cool gases, and many liquids and solids, are recognized by the characteristic dark lines of their absorption spectra (see phrase), which in the case of a gas correspond exactly in position with those of the emission spectrum it would produce if it were incandescent In chemistry, substances to be analyzed are vaporized and heated to incandescence in a hot flame or in the electric arc, or, if they are to be examined by their absorption, are placed between the spectroscope and a bright light Minute quantities that would evade chemical analysis can thus be detected easily and certainly The spectra of celestial objects are examined by means of an analyzing spectroscope, and by the careful comparison of these celestial spectra with spectra of the known terrestrial substances it has been found possible to prove the existence of such substances in the sun and stars and to classify the latter into certain allied groups See STAR TYPE By observation of the shifting of the spectral lines it is also possible to measure the velocity of stars in the line of sight (See DOPPLER'S PRINCIPLE, under PRINCIPLE) Much labor has been spent upon determining the characteristic spectra of the chemical elements, their changes under varying physical conditions, their presence in the sun and the stars, and the development occurring in individual stars as noted by the comparison of such changes

The most common form of spectrum is that produced by the light of the sun passing through a triangular glass prism and falling on a screen The component colors, being unequally refracted are spread out into a band displaying the seven rainbow colors, having the red at one end (that of least deviation) and the violet at the other The same

effect is produced by reflection from or passage through a diffraction grating (See DIFFRACTION) Instead of being received on a screen, the spectrum may be viewed directly with a telescope (See SPECTROSCOPE) The spectrum is not limited to the visible part There is an invisible spectrum below the red (*the infra-red spectrum* or *dark heat-spectrum*) and one above the violet (*the ultra-violet spectrum*), both of which can be detected by photography and by other physical processes Different media disperse the rays in varying degrees in different parts of the spectrum, while the gratings do not, hence the spectra due to refraction are called *abnormal*, and those due to diffraction *normal* Solid and liquid bodies, when incandescent, give out *continuous spectra*, gaseous bodies give out *line*, *band*, or *fluted spectra*, according to the degree of their density If light from an incandescent solid passes through gas at a lower temperature or through some solids and liquids, some rays are absorbed, producing *absorption spectra* See phrases below **2.** An after-image **3†.** An apparition [L, see SPECTER] —**absorption spectrum,** *the spectrum of light that has* undergone selective absorption by passing through a gas or other partially transparent medium commonly characterized by dark lines showing the wave-lengths of the absorbed light —**actinic s**, a spectrum consisting only of the actinic or ultra-violet rays which are especially capable of chemical action —**atmospheric s**, the spectrum formed by the dispersion and refraction of a beam of light by its passage through the atmosphere —**band s**, a spectrum apparently composed of dark or bright bands, intense at one edge and fading off toward the other Powerful instruments *show that each band is made up of many fine parallel lines*, very close together at one edge of the band, the distances apart regularly increasing toward the other Absorption spectra show dark bands that can not be resolved into lines —**channeled s**, same as FLUTED SPECTRUM —**chemical s**, same as ACTINIC SPECTRUM —**chromatic s.**, a spectrum consisting only of the visible rays, the different wave-lengths of the light being shown by their colors —**comparison s**, a spectrum formed in the field of vision of a spectroscope either directly above or below the principal spectrum for the purpose of comparison —**continuous s.**, a spectrum in which the different colors fade into each other by insensible gradations, no lines or bands, whether dark or bright, being present —**diffraction s.**, a spectrum produced by diffraction, especially by the reflection of light from or its passage through a diffraction grating —**electric s. 1.** That part of the spectrum of which the rays are electrical in character **2.** A spectrum produced by an electric arc, an electric discharge through rarefied gas, etc —**emission s**, a spectrum regarded as characterizing the body that emits the rays rather than one through which they pass opposed to *absorption spectrum* —**flame s**, a spectrum produced by a substance when volatilized in a colorless flame —**fluted s**, a spectrum in which the intensity of the light is so graduated *that it appears as if transversely* channeled or fluted —**gas or gaseous s**, a spectrum formed from the rays emitted by an incandescent gas generally consisting of a limited number of bright lines, separated by dark spaces —**heat s**, a spectrum consisting only of heat or infra-red rays especially one formed by non-luminous radiant energy —**line s**, a spectrum of isolated narrow lines, as of an incandescent vapor —**magnetic s**, the appearance noted when cathode rays deflected by a magnet, strike a phosphorescent screen —**meteor s**, the spectrum resulting from the diffused light of a meteor —**normal s**, a spectrum in which an exact geometric relation between the wave-length of the light and its position in the spectrum may be established, especially, a diffraction spectrum —**ocular s. 1** Same as SPECTRUM, 2 **2.** Same as CHROMATIC SPECTRUM —**prismatic s**, the spectrum produced by the dispersion of light by a prism —**pure s**, a spectrum in which the overlapping of the monochromatic spectral images of the spectroscopic slit produces no appreciable intermingling of the color-tones The purity of such a spectrum increases with the diminution in width of the slit —**solar s**, the spectrum formed from the rays of the sun an absorption spectrum characterized by thousands of fine dark lines, called Fraunhofer's lines, arranged in a large number of groups See LINE, *n*, 23 (2) —**spark s**, a spectrum given by the incandescent gases and vapors in an electric spark —**s analysis**, same as SPECTROSCOPY —**thermal s**, same as HEAT SPECTRUM —**visible s.**, *same as* CHROMATIC SPECTRUM

TABLE OF COLORS

In the table of *standardized colors*, opposite, the columns headed Bk, W, R etc contain the percentages of black, white, red orange, yellow, green, and blue, respectively, that compose the color given in the first column Superior figures refer to approximate synonyms and definitions of unusual colors *which are given in the note at foot of page* The wave-lengths of the standard colors in microns are as follows red, 0 644, orange, 0 614 yellow, 0 585, green 0 521 blue, 0 452 To obtain the desired color, its components must be blended, not by mixing pigments, which will not give the proper result, but in the following manner Seven standard disks must be prepared, each from 3 to 5 inches in diameter, with a small hole at the center for the axis and a radial cut from center to periphery The white disk must be of the purest white cardboard, the others should be cut from light cardboard or heavy drawing-paper, and painted each with its proper color For the black disk use a mixture of the best lampblack in a solution of shellac in alcohol, applying it with a bristle brush like an oil-paint Experiment will show the proper proportions to leave the surface even, firm, and dull The remaining five disks are to be painted respectively with the best English vermilion mineral orange, light chrome yellow, emerald-green, and artificial ultramarine blue The pigments should be mixed with a thick solution of gum arabic in water, to the consistency of oil-paint, and applied with a bristle brush The color must be even and the paper completely covered

To prepare any color from the equivalents given in the table, put the required disks upon the axis of any rotation-machine, as a *color-wheel*, *color-top*, or *color-mixer*, with the edges of the slits so interposed that a sector of each disk is visible, then, by means of a cardboard circle divided on *its edge into hundredths, arrange the relative proportions* of the standard colors according to the formula given in the table When the wheel or top is set in rapid rotation, the required color will result from the blending of the components

In a few cases the colors are too brilliant to be matched with the disks under these circumstances the brilliancy is reduced by blending with the color a certain percentage of black or white, as given in the first columns, this modified hue is then matched by the formula given in the remaining columns, for example, 83 red and 17 blue will match rose lake blended with 30 parts of black Colors shown in the colored plate are designated in the table on the opposite page by an asterisk, and often differ slightly from the most generally accepted hues of the same names, which are also given in most cases

In all the Metazoa the prevailing method of reproduction is by the union of two 'sexually differentiated germ-cells or gametes', a small motile microgamete' or *spermatozoon* and a large yolk-laden macrogamete' or ovum This differentiation between the germ-cells is another example of the advantages of division of labour for while the onus of bringing about the union of the germ-cells is thrown entirely on the *spermatozoon* the egg devotes itself to the accumulation of food-material for the subsequent use of the developing embryo The fundamental physiological difference which this division of labour has produced in the germ-cells is reflected on to the general metabolism of the parents and underlies the sexual differentiation of the latter *Encyc Brit* 11th ed, vol vii p 717.

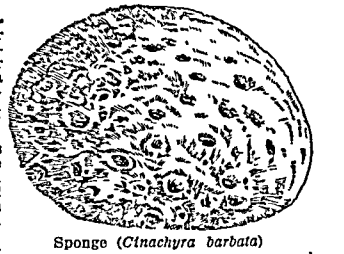
sponge, *n* **1.** An animal with pores in the body-wall and without tentacles, one of the *Porifera*



The simplest known sponge is a vase-like sac attached by its blind end, with an osculum at the free end and has thin walls of which the endoderm or inner layer consists of collar-cells which resemble choanoflagellate infusorians In the higher sponges the pores open into much-branched afferent canals passing to the ciliated chambers to which the collar-cells are restricted and from which efferent canals lead into the central cavity, this opening outward by the osculum Water laden with food (minute organisms) enters the pores in a constant stream maintained by the action of the flagella of the collar-cells, and passes out with the waste particles by the osculum Sponges live fixed to other objects or rooted in mud, and are mostly marine Reproduction is asexual by external or internal budding or sexual, by eggs and spermatozoa Skeletal structures or spicules, consisting of calcium carbonate, of silica, or of horn (spongin), are formed in the mesoderm

Sponges are found fossil in a great variety of rocks some with a kind of simple skeleton of limestone others with flint and some merely horny without much mineral
